UNIVERSITY

# Review

## Evaluation Techniques

### Evaluating Without Users

- E1 Literature Review
- E2 Cognitive Walkthrough
- E3 Heuristic Evaluation
- E4 Model-based Evaluation
  - GOMS, HCI Design Patterns, ...

### Evaluating With Users

#### Qualitative

- E5 Model Extraction
- E6 Silent Observation
- E7 Think Aloud
- E8 Constructive Interaction
- E9 Retrospective Testing

#### Quantitative

- E10 Controlled Experiments

+ Interviews, questionnaires,...

- Evaluation:
  - When, why, where?
  - Evaluation techniques?
- Participatory Design
- How to deal with users?

# GOMS

# A Story

- In 1995, now-famous web guru Jakob Nielsen had less than 24 hours to recommend if adding three new buttons to Sun's home page was a good idea.
  - Check out his [articles at the Nielsen Norman Group](#) for good (and often fun) web design advice
- He found that each new, but unused button costs visitors 0.5 million \$ per year.
- 2 of the 3 new buttons were taken back out.
- The method he used for his estimate: GOMS.

# GOMS

- **G**oals, **O**perators, **M**ethods, **S**election rules
- In Card, Moran, Newell: The Psychology of HCI, 1983
- To estimate execution and learning times *before* a system is built

# GOMS: Components

- **Goals** describe users' end goals
  - Routine tasks, not too creative/problem-solving
    - E.g., “copyedit manuscript”
  - Leads to hierarchy of subgoals
- **Operators** are elementary user actions
  - Key presses, menu selection, drag & drop, reading messages, gestures, speech commands, ...
  - Assign context-independent duration (in ms)
- **Methods** are “procedures” to reach a goal
  - Consist of subgoals and/or operators
- **Selection rules**
  - Which method to use for a (sub)goal
    - E.g., to delete some text (individual preferences apply!)

# Sample Method and Operators in Copyediting

GOAL: HIGHLIGHT-ARBITRARY-TEXT

A. MOVE-CURSOR-TO-BEGINNING	1.10s
B. CLICK-MOUSE-BUTTON	0.20s
C. MOVE-CURSOR-TO-END	1.10s
D. SHIFT-CLICK-MOUSE-BUTTON	0.48s
E. VERIFY-HIGHLIGHT	1.35s

# GOMS Variants

- **GOMS** (Card, Moran, and Newell 1983)
  - Model of goals, operators, methods, selection rules
  - Predict time an experienced worker needs to perform a task in a given interface design
- **Keystroke-level model** (simplified version)
  - Comparative analyses of tasks that use mouse (GID) and keyboard
  - Correct ranking of performance times using different interface designs
- **CPM-GOMS** (critical path method)
  - Computes accurate absolute times
  - Considers overlapping time dependencies
- **NGOMSL** (natural GOMS language)
  - Considers non-expert behavior (e.g., learning times)

# KLM: Keystroke-Level Model

- Execution time for a task = sum of times required to perform the serial elementary gestures of the task
- Typical gesture timings
  - **Keying**  $K = 0.2$  s (tap key on keyboard, includes immediate corrections)
  - **Pointing**  $P = 1.1$  s (point to a position on display)
  - **Homing**  $H = 0.4$  sec (move hand from keyboard to mouse or v.v.)
  - **Mentally preparing**  $M = 1.35$  sec (prepare for next step, routine thinking)
  - **Responding**  $R$  (time a user waits for the system to respond to input)
- Responding time  $R$  effects user actions
  - Causality breakdown after 100 ms
  - User will try again after **250 ms**  $\Rightarrow R$
  - Give feedback that input received & recognized

# Keystroke-Level Calculation

- List required gestures
  - E.g., HK = move hand from mouse to keyboard and type a letter
- Compute mental preparation times Ms
  - Difficult: user stops to perform unconscious mental operations
  - Placing of Ms described by rules
- Add gesture timings
  - E.g., HMPK = H + M + P + K = 0.4 + 1.35 + 1.1 + 0.2 = 3.05 sec
- Rule terminology
  - **String:** sequence of characters
  - **Delimiter:** character marking beginning (end) of meaningful unit
  - **Operators:** K, P, and H
  - **Argument:** information supplied to a command

# Rules for Placing Ms

- Rule 0, initial insertion for candidate Ms
  - Insert Ms in front of all Ks
  - Place Ms in front of Ps that select commands, but not Ps that select arguments for the commands
- Rule 1, deletion of anticipated Ms
  - Delete M between two operators if the second operator is fully anticipated in the previous one
    - E.g., PMK  $\Rightarrow$  PK
- Rule 2, deletion of Ms within cognitive units (contiguous sequence of typed characters that form a name)
  - In a string of MKs that form a cognitive unit, delete all Ms except the first
    - E.g., “dir”  $\Rightarrow$  MK MK MK  $\Rightarrow$  MK **K K**

# Rules for Placing Ms

- Rule 3, deletion of Ms before consecutive terminators
  - If K is redundant delimiter at end of a cognitive unit, delete the M in front of it
    - E.g., “bla↵↵” ⇒ M 3K MK MK ⇒ M 3K MK K
- Rule 4, deletion of Ms that are terminators of commands
  - If K is a delimiter that follows a constant string then delete the M in front of it (not for arguments or varying strings)
    - E.g., “clear↵” ⇒ M K K K K K MK ⇒ M K K K K K K

Note that the ‘clear’ command does not take any arguments, and is therefore a constant string. ‘ls,’ on the other hand, can take arguments and Rule 4 cannot be applied there.
- Rule 5, deletion of overlapped Ms
  - Do not count any M that overlaps an R
    - E.g., user waiting for computer response

# Exercise: Temperature Converter

- Convert from degrees Fahrenheit (F) to Celsius (C) or vice versa, requests equally distributed
- Use keyboard or mouse to enter temperature
- Assume active window awaiting input, an average of four typed characters (including point and sign), and no typing errors
- Task: create and analyze your own interface!

# The Dialog Box Solution with Radio Buttons...

# ...And Its Keystroke-Level Model

- Case 1: select conversion direction
  - Move hand to mouse, point to desired button, click on radio button (HPK)
  - Move hands back to keyboard, type four characters, tap enter (HPK HKKKK K)
  - Rule 0 (insert M's): (HMPMK HMKMKMKMK MK)
  - Rule 1 (deletion of anticipated M's): (HMP\_K HMKMKMKMK MK)
  - Rule 2 (deletion of M's within cog. units): (HMP\_K HMK\_K\_K\_K MK)
  - Result: HMPK HMKKKK MK
  - Estimated time = 7.15 sec
- Case 2: correct conversion direction already selected
  - MKKKMK = 3.7 sec
- Average time =  $(7.15 + 3.7) / 2 = 5.4$  sec

# GOMS Results

- Execution (& learning) times of trained, routine users for repetitive tasks (goals), leading to cost of training, daily use, errors
  - Can be linked to other costs (purchase, change, update system), resulting in \$\$\$ answers
  - Use to model alternative system offers
    - E.g., “new NYNEX computers cost \$2M/year more” [Gray93]
- Estimate effects of redesign
  - Training cost vs. long-term work time savings
- Starting point for task-oriented documentation
  - Online help, tutorials, ...
- Don't use for casual users or new UI techniques
  - Operator times not well defined

# Information Efficiency

# Measuring Interface Efficiency

- How fast can you expect an interface to be?
- **Information** as quantification of amount of data conveyed by a communication (Information theory)
  - E.g., speech, messages sent upon click...
- Lower bound on amount of information required for task is independent of interface design
- Information-theoretic efficiency  $E = \frac{\text{Minimal info required for the task}}{\text{Info supplied by user}}$ 
  - $E \in [0, 1]$  (e.g.,  $E = 0$  for providing unnecessary information)
- **Character efficiency** =  $\frac{\text{Minimal number of characters required for the task}}{\text{Number of characters entered in the UI}}$

[Jef Raskin: The Humane Interface, 2000]

# Quantify Amount of Data

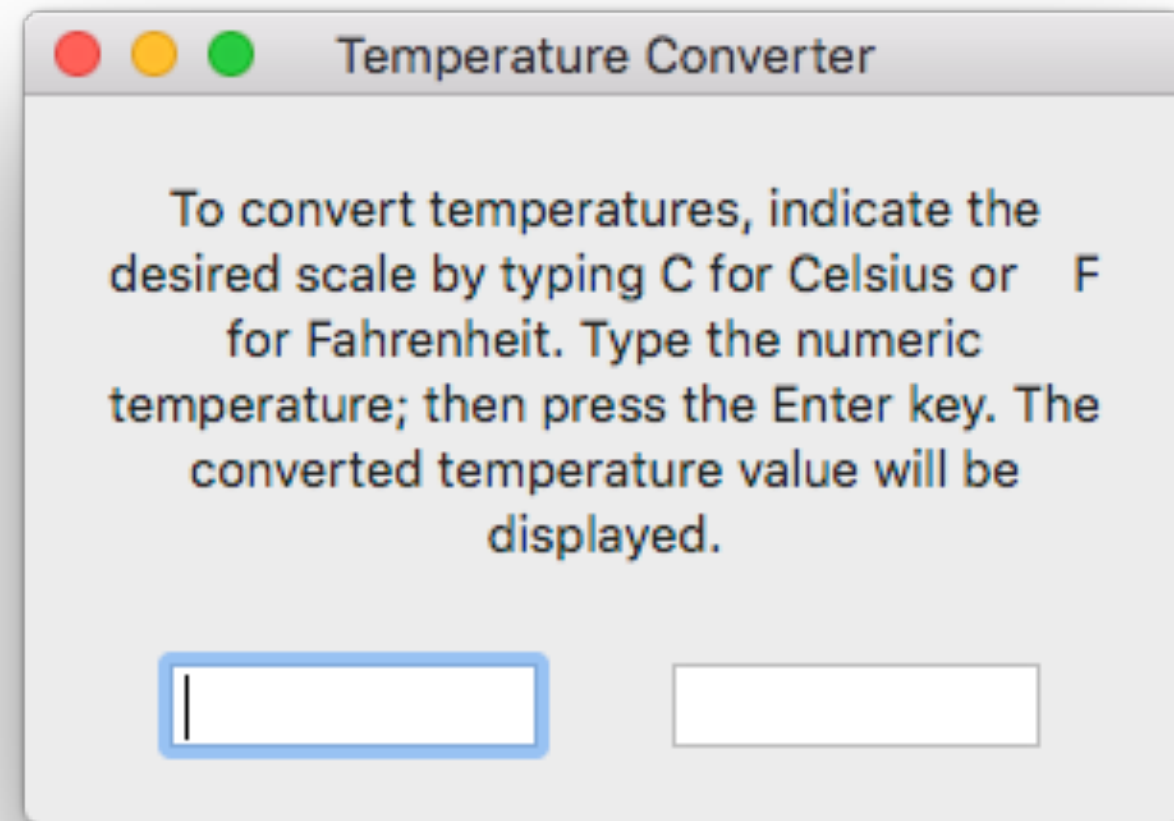

- Information is measured in bits
  - 1 bit represents choice between 2 alternatives
- $n$  equally likely alternatives
  - Total information amount:  $\log_2(n)$
  - Information per alternative:  $\frac{1}{n} \log_2(n)$
- $n$  alternatives with different probabilities  $p(i)$ 
  - Information per alternative:  
$$p(i) \cdot \log_2\left(\frac{1}{p(i)}\right)$$
  - Total amount = sum over all alternatives
- Consider situation as a whole
  - Probability of messages required
  - Information measures freedom of choice (information  $\neq$  meaning)

# Example: Temperature Converter

- Input assumptions (given)
  - 50% Fahrenheit, 50% Degree Celsius
  - 75% positive, 25% negative
  - only decimal input (no integer numbers)
  - All digits are equally likely
  - Only four characters input

# Example: Temperature Converter

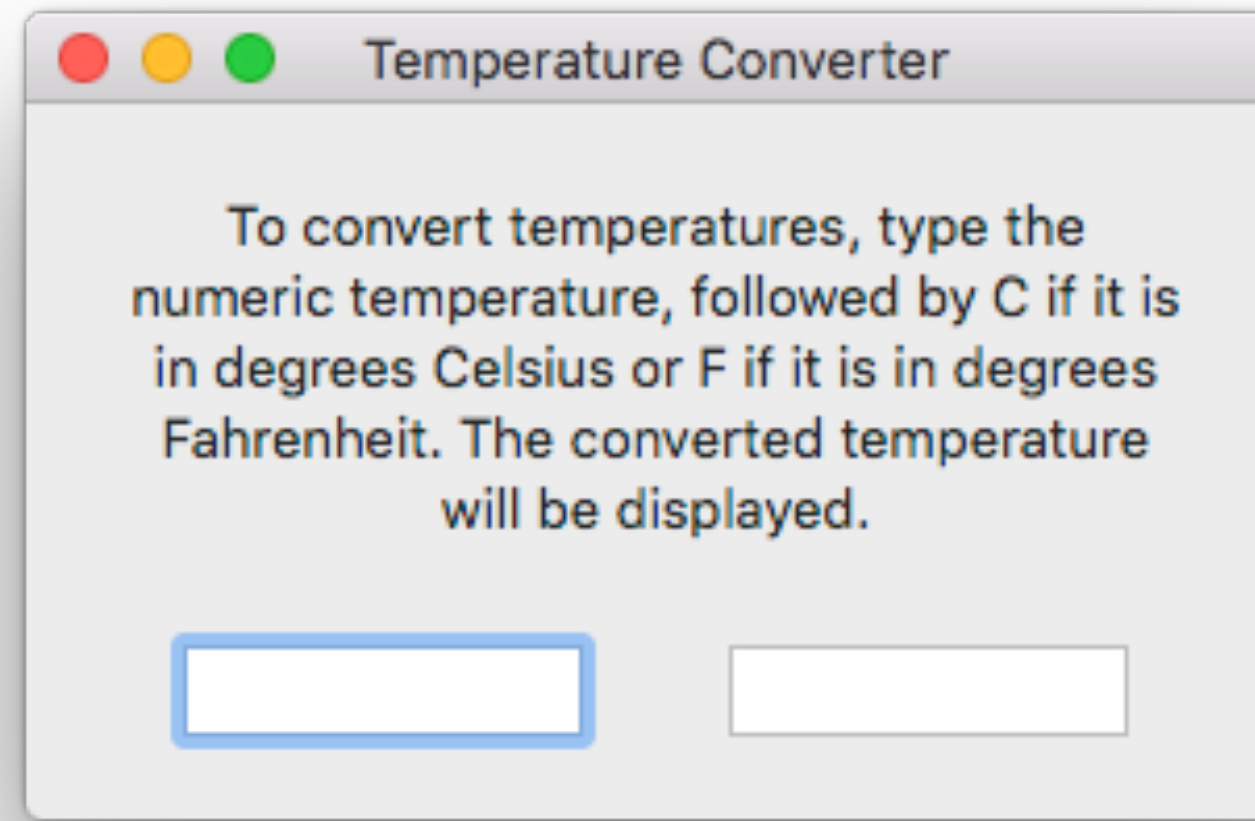

Type C or F, value, enter

M K K K K M K

3.9s char. eff. 67%

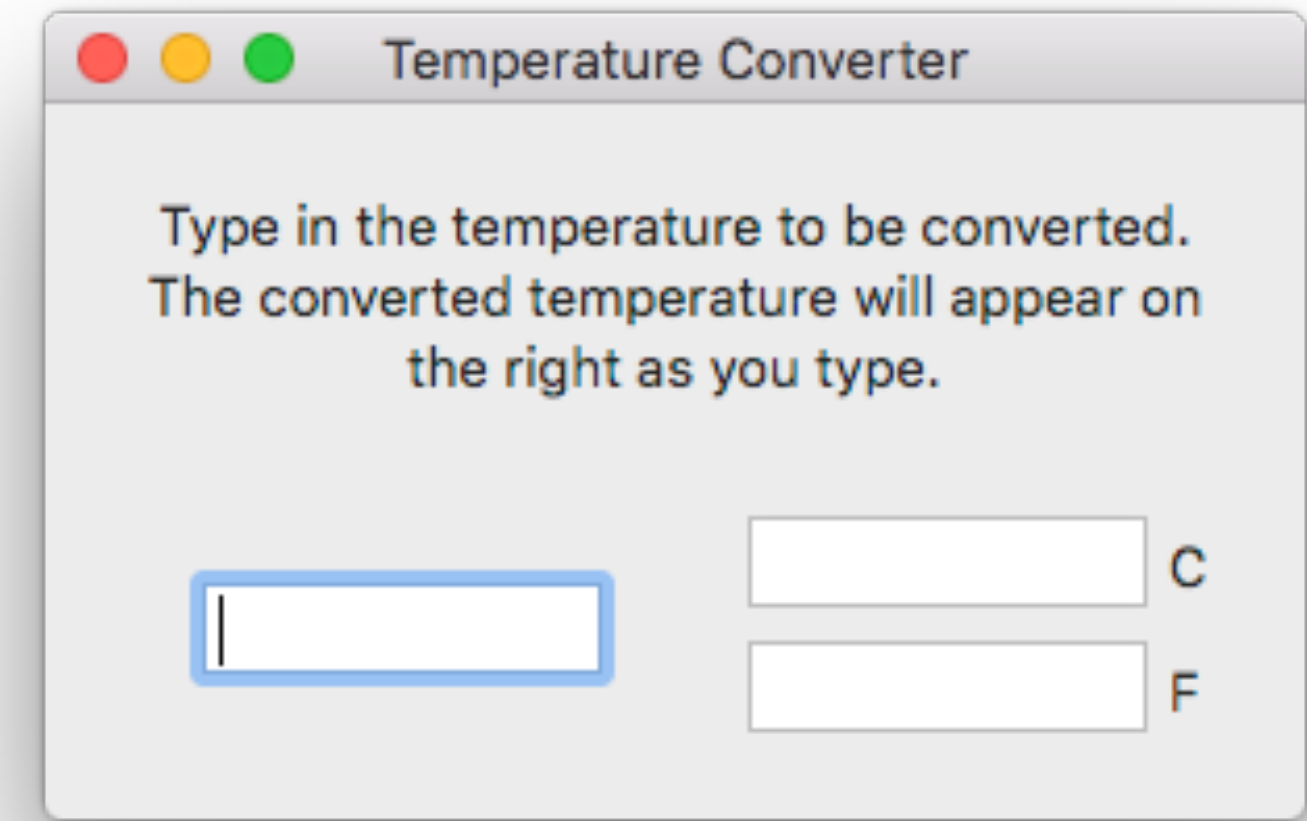

Type value, then C or F

M K K K K M K

3.7s char. eff. 80%

Bifurcated

M K K K K

2.15s char. eff. 100%

# Example: Temperature Converter

Information per alternative:  
$$p(i) \cdot \log \frac{1}{p(i)}$$

Numbers	Prob.	Values	$p(i)$	Information in bits	Overall (values × information in bits)
-.dd	12,5 %	100	0,00125	0,012	1,2
-d.d	12,5 %	100	0,00125	0,012	1,2
.ddd	25 %	1000	0,00025	0,003	3
d.dd	25 %	1000	0,00025	0,003	3
dd.d	25 %	1000	0,00025	0,003	3

⇒ Minimal info required for the task = 11.4 bits/message

⇒ Simple approach:  $4 \log_2(12) \approx 14$  bits

# Example: Temperature Converter

- Information efficiency:  $E = \frac{11.4 \text{ bits}}{\text{Info supplied by user}}$ 
  - 128 keys standard keyboard (~5 bits/key in practice):  $E = \frac{11.4}{4 \cdot 5} \approx 55 \%$
  - 16 keys numeric keypad:  $E = \frac{11.4}{4 \cdot 4} \approx 70 \%$
  - 12 keys dedicated keypad:  $E = \frac{11.4}{4 \cdot 3.6} \approx 80 \%$
